Background and aims

Mongolia has the highest prevalence of hepatitis D virus (HDV), leading to high morbidity and mortality from liver diseases and hepatocellular carcinoma (HCC). HDV causes the most severe form of chronic viral hepatitis. In a recent study, it was estimated that anti-HDV prevalence is 67.5% among HBsAg positive population in Mongolia. However, updates on the incidence of and risk factors for acute hepatitis D infection in Mongolia are lacking. Therefore, our aim was to determine prevalence of acute HDV incidences among Mongolian youths aged between 15-35 years old.

Methods

A retrospective study was carried out reviewing records for all acute HBV and HDV cases admitted between 2010-2014 at the National Center for Communicable Disease of Mongolia.

Results

A total of 1973 patients were admitted to the National Center for Communicable Disease of Mongolia due to acute HBV and HBV/HDV over the last 5 years. Overall prevalence of acute HBV/HDV was 30.8% (608 inpatients, age 0.2-49), while 27.7% among 15 to 35 years old (Figure 1) and predominantly male (67.6%).

As shown in Figure 1, 89.9% (547) of all acute HDV cases were accounted for 15 to 35 years old youths, especially 21 (13%), 22 (10.4%), 23 (8.9%), 24 (10.1%), 25 (9.9%) and 26 (7.3%) years olds. At the time of admission, average ALT and AST were 2172.7 U/L and 1462.6 U/L, respectively. At the time of discharge, it was decreased to 127.8 U/L (ALT) and 108.7 U/L (AST).

Conclusion

Incidences of acute HDV infection among the Mongolian population is high, especially those 15-35 years old population. It clearly demonstrates that more work is required to control and prevent this serious condition.
needs to be done to prevent new HBV/HDV infections.
